DESIGN, FABRICATION, AND FABRICATION EVALUATION
OF HIGH TEMPERATURE FUEL PINS

By
R. L. Gulley

ABSTRACT

A total of twenty-seven molybdenum clad fuel pins were designed and fabricated by Battelle-Northwest for the Lewis Research Center of the National Aeronautics and Space Administration. The purpose of the pins is to provide irradiation data needed for the design of full-length reactor fuel pins. Six of the fuel pins contained depleted uranium dioxide (UO_2); fourteen contained fully enriched UO_2 ; one contained depleted uranium nitride (UN); and six contained fully enriched UN .

DESIGN, FABRICATION, AND FABRICATION EVALUATION
OF HIGH TEMPERATURE FUEL PINS

INTRODUCTION

Battelle-Northwest has completed a program to design and fabricate high temperature fuel pins for the Lewis Research Center of the National Aeronautics and Space Administration.⁽¹⁾ This report, the fifth and final of a series^(2,3,4,5) required in this contract, describes the design, fabrication, and fabrication evaluation of the fuel pins.

SUMMARY

A total of twenty-seven molybdenum clad fuel pins were fabricated for tests and evaluation. Six of these fuel pins were prototypes and contained depleted uranium dioxide (UO_2); fourteen contained fully enriched UO_2 ; one contained depleted uranium nitride (UN); and six contained fully enriched UN. A number of short pellets were used to make up each UO_2 fuel column, and a single pellet was used for each UN fuel column. All of the pins met the required criteria and quality levels established for the design irradiation conditions. Pertinent data for each pin are presented in Table I. Design specifications for the fuel pins are presented in Drawing No. R-1008 (Figure 1).

The purpose of these pins is to provide irradiation data needed for the design of full-length reactor fuel pins. Primary factors considered in the design of these pins for high temperature service to high exposure include:

Λ P - Prototypic

- ° Maximum cladding and fuel temperatures
- ° Fuel expansion
- ° Internal pressures due to released fission gas
- ° Heat transfer from the fuel to the coolant
- ° Compatibility of the cladding with the fuel material and the coolant

Although it was necessary to develop techniques for fabricating the cored UN pellets, no significant problems were encountered in fabricating the pellets. Problems were encountered, however, with the cladding. Attempts to bore out stock molybdenum tubing to obtain a thin wall (0.025 in.) cladding failed to hold wall thickness and internal surface requirements. To eliminate the machining problems, a thick wall (0.050 in.) tubing was specified by NASA-Lewis. Adoption of the thick wall tubing introduced a weld penetration problem which was eventually corrected by altering the end cap design and developing a welding technique.

Significant aspects of the work performed under this contract were:

- ° A fuel pin design which met the criteria established by NASA-Lewis was developed.
- ° The fuel pins were fabricated to required criteria and quality levels.
- ° Cored UO_2 pellets with thin walls were fabricated to close tolerances.
- ° Solid and cored UN pellets were fabricated by hot isostatic compaction.
- ° A source of high quality TZM molybdenum alloy cladding tubes was established.
- ° A welding technique for making the fuel pin end closures was developed.

DESIGN OF THE FUEL PINS

The fuel pins described in this report were designed to provide irradiation data needed for the design of full-length reactor fuel pins. Primary factors considered in the design of these pins for high temperature service to high exposure include:

- ° Maximum cladding and fuel temperatures
- ° Fuel expansion
- ° Internal pressure due to released fission gas
- ° Heat transfer from the fuel to the coolant
- ° Compatibility of the cladding with the fuel material and the coolant.

Fuel Material and Form

Pelleted UO_2 was used in one of the basic fuel pin designs because of the large amount of experience and confidence that has been acquired with this type of fuel. The technology of this material is well advanced and its adequacy as a reactor fuel has been thoroughly demonstrated. Pelleted UN was used in one of the basic fuel pin designs because pelleted UN can be operated at higher powers without reaching excessive fuel temperatures than can pelleted UO_2 . The thermal conductivity of UN is about six times that of UO_2 .

Solid pellets and cored pellets were used in the fuel pin designs. Cored pellets allow for a shorter gas plenum than solid pellets because fuel temperatures are lower and fewer fission gases are released from the fuel. Solid pellets were used because of the large amount of experience with this form of fuel and the ease with which they can be fabricated.

Cladding Material

The operating conditions of these fuel pins required that a refractory metal be used for cladding. Tungsten, molybdenum, niobium, and tantalum were considered as candidate cladding materials. Based on neutronic, thermal, and strength properties, molybdenum was chosen to be the best suited cladding material. In addition, molybdenum is compatible with the fuel materials and coolant to which the cladding is to be exposed.

Fuel-to-Cladding Gap and Bond

The gap between the fuel and cladding was chosen so that differential expansion of the fuel and cladding would permit the pellets to contact the cladding but exert zero interface pressure at maximum operating conditions. The two components that comprise fuel expansion are thermal expansion and fission product swelling. Calculation of total fuel expansion was made on a conservative basis by using high values for thermal expansion and swelling rate.

One atmosphere of helium gas was used in these fuel pins to provide a heat transfer bond between the fuel and the cladding. Although experience has shown⁽⁶⁾ that the generation and release of fission gases quickly provides a gaseous heat transfer bond and a corresponding reduction in fuel temperature, calculations show that almost all of the fuel in these pins would initially be molten if they were fabricated without a gas bond.

Helium gas, rather than nitrogen gas, was used in the fuel pins containing UN pellets because the thermal conductivity of helium is significantly (~5 times) higher than that of nitrogen. Consideration was given to the dependence of

UN decomposition on nitrogen pressure. Calculations, based upon experimental data⁽⁷⁾, showed that for a fuel pin containing a 10.5 gram UN pellet and a 0.047 cu. in. (0.2 in. diameter by 1.5 in. long) gas plenum less than 0.0008% of the UN would decompose when at 2500°C and less than 0.08% would decompose when at 2850°C.

Cladding Thickness and Gas Plenum Length

Factors considered in arriving at a minimum cladding thickness included an estimate of the maximum internal pressure and an allowable cladding stress. The allowable stress was assumed to be equal to one-half the ultimate tensile strength reported by Brookes and Harris.⁽⁸⁾ The maximum internal pressure was estimated by selecting a gas plenum length, based upon pin dimension limitations specified by NASA-Lewis⁽¹⁾, and assuming that all of the fission gases formed and the helium bond gas will be collected in the plenum. The average temperature of the gases was assumed to be the same as the maximum cladding temperature specified by NASA-Lewis.⁽¹⁾

DESCRIPTION OF THE FABRICATION PROCESS

Flowsheets of the UO_2 and UN pellet preparation processes are presented in Figures 2 and 3, respectively. A flowsheet of the fuel pin fabrication process is presented in Figure 4.

Pellet Preparation

The UO_2 pellets were prepared by well-established cold pressing and sintering techniques. A detailed description of the basic process is presented in Special Report No. 2.⁽³⁾ Ceramic grade UO_2 powder, which was purchased from a commercial vendor, was mixed with water and a binder

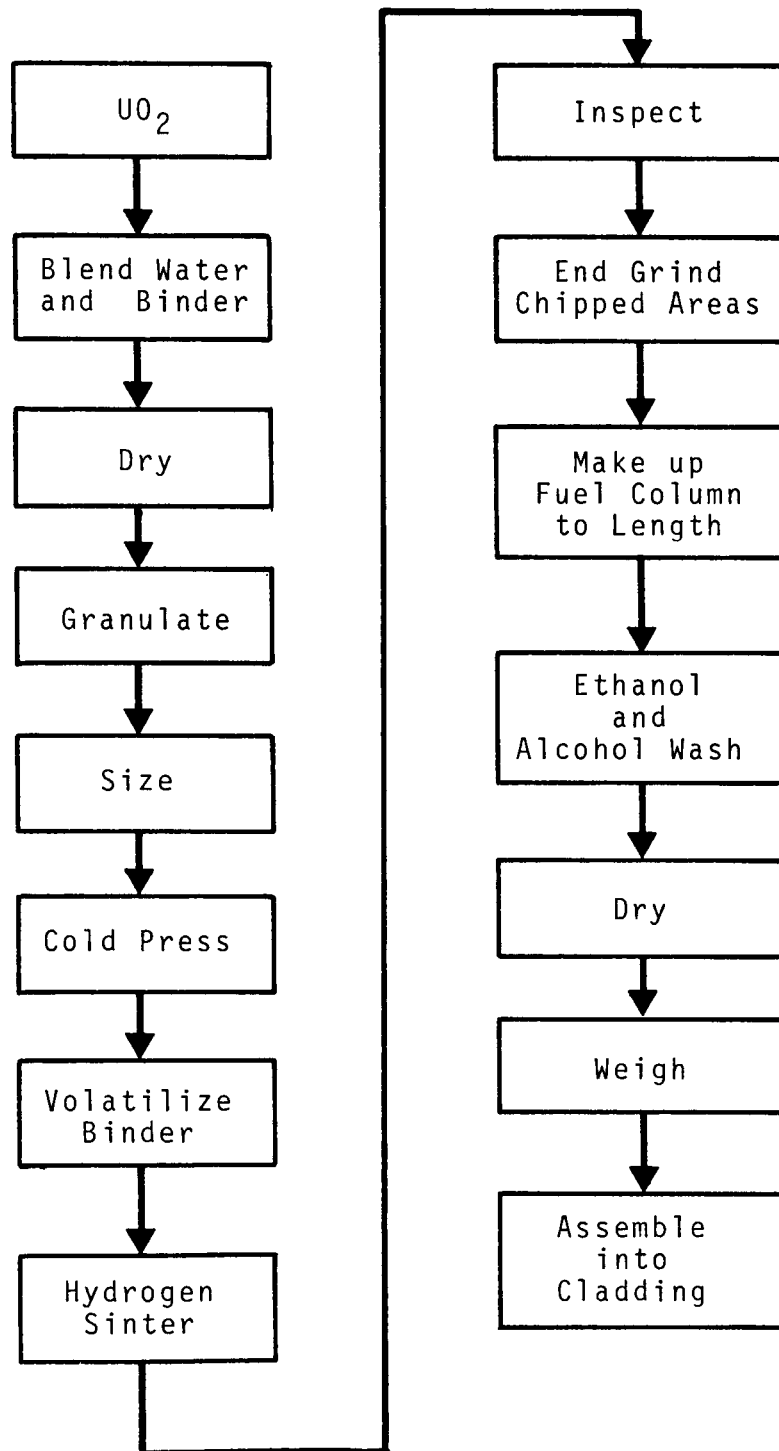

FIGURE 2. UO₂ Pellet Preparation Process

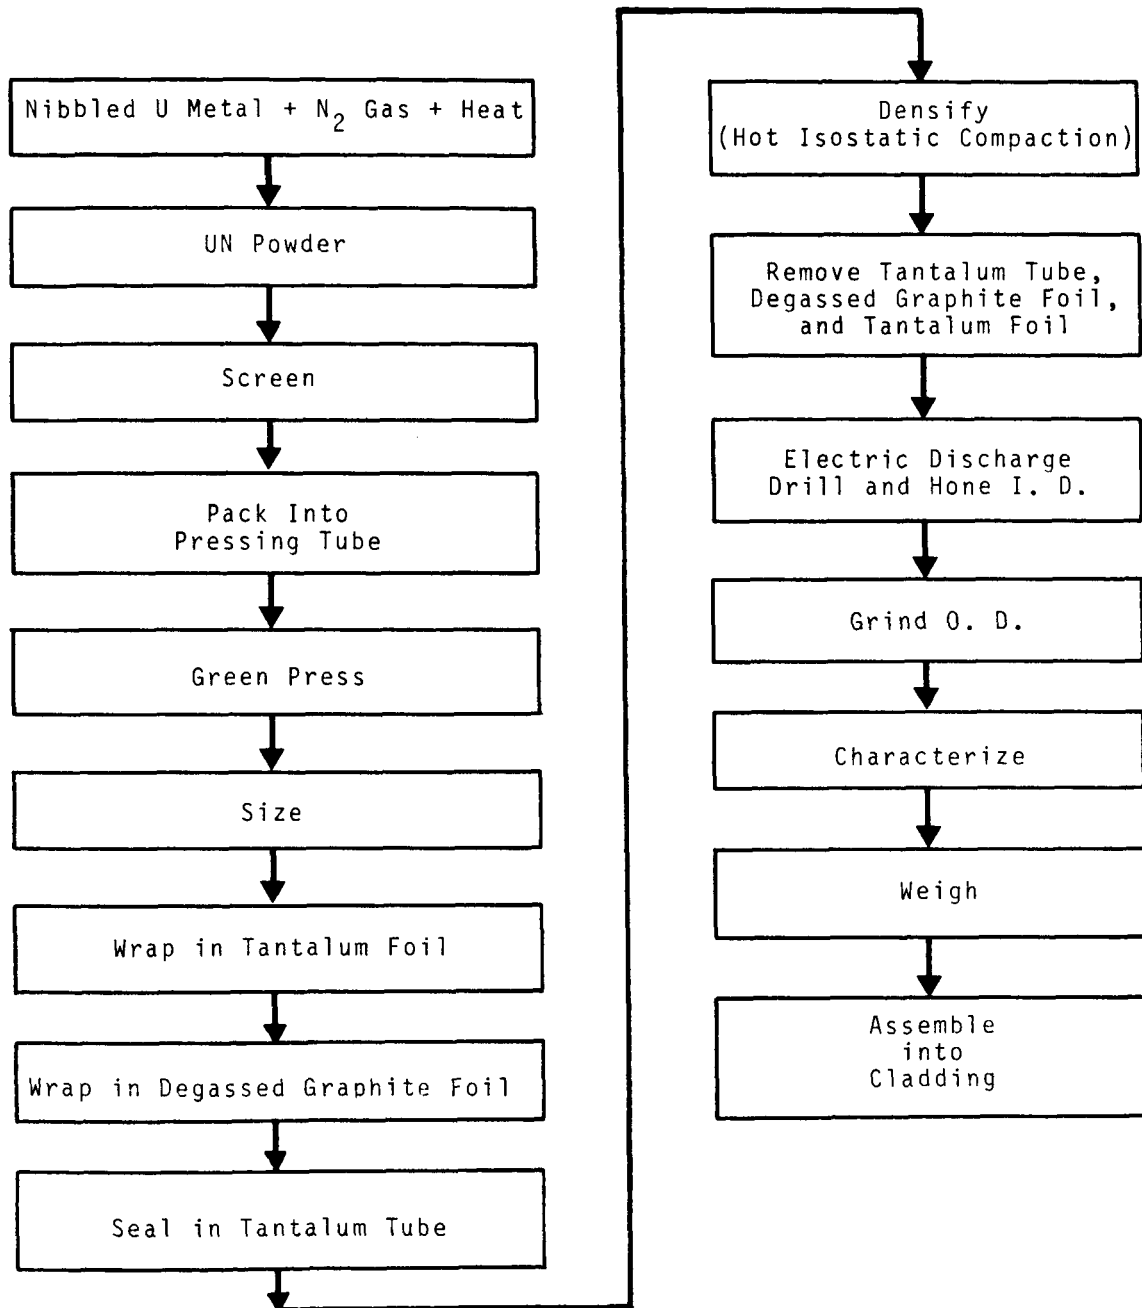

FIGURE 3. UN Pellet Preparation Process

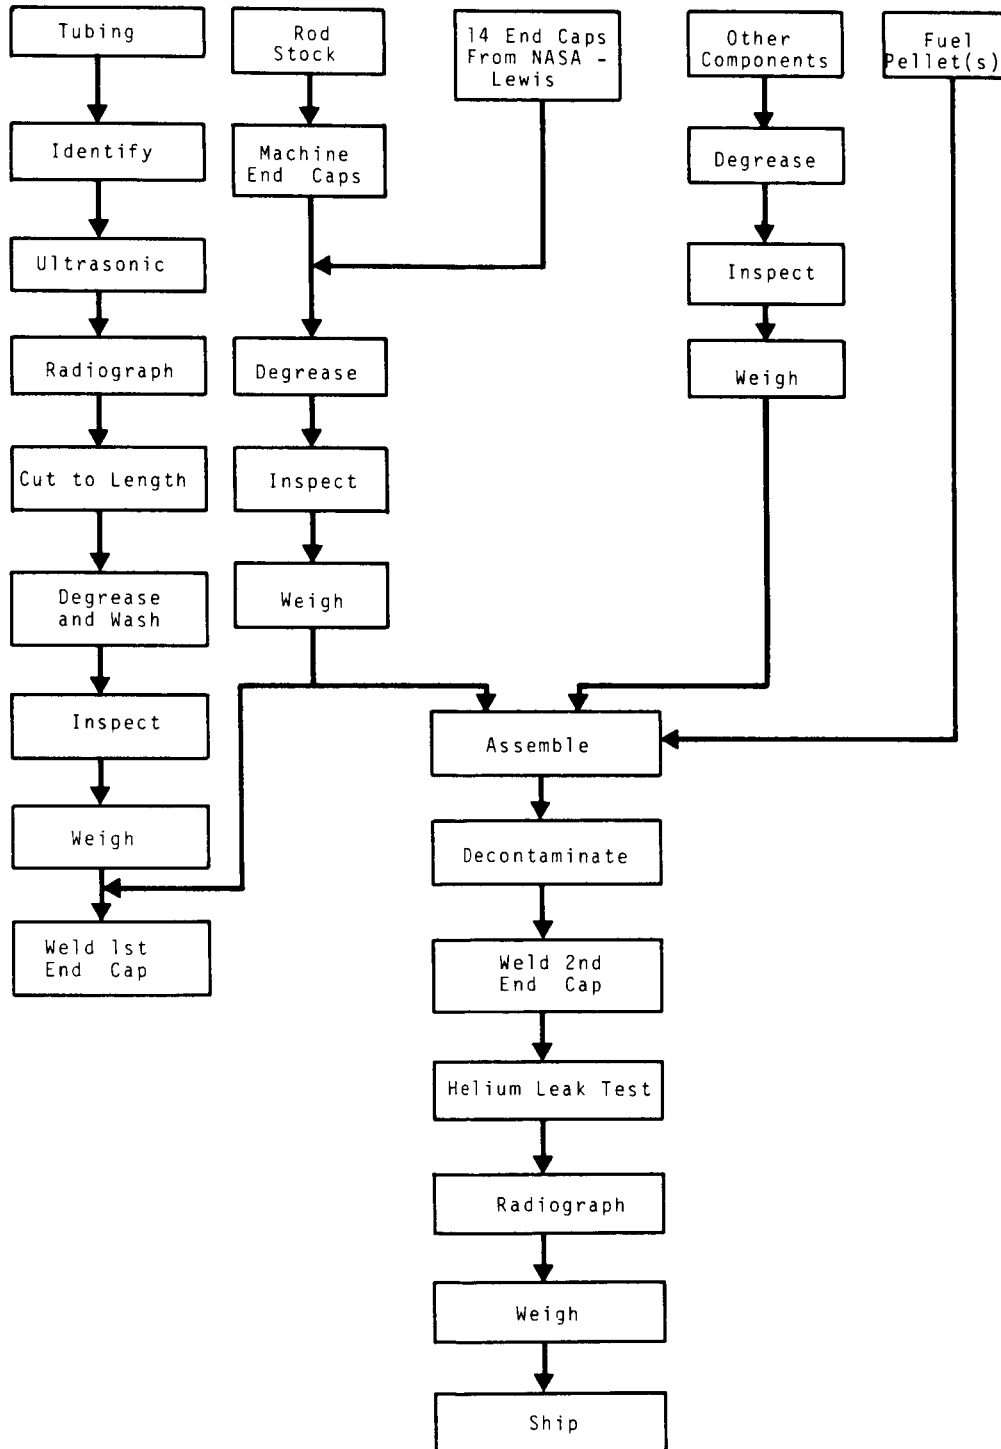

FIGURE 4. High Temperature Fuel Pin Fabrication Process

(Carbowax) to form a slurry. The slurry was dried, granulated, and sized. The pellets were cold pressed at 90,000 psi to a green density of 56-60% of theoretical and then sintered in hydrogen at 1680°C for eight hours. Because the sintering characteristics of the UO_2 powder had been determined and the pressing and sintering conditions carefully controlled, no grinding was necessary to obtain the desired diameter. The sintered pellets varied from 94-96% T.D. Pellets were end-ground, as necessary, to remove chipped areas. Fuel columns were fabricated to exact length by grinding the final pellet. After grinding, the pellets were washed in ethanol and dried.

The UN pellets were fabricated at the Battelle Memorial Institute Laboratories in Columbus, Ohio. Six cored pellets of polycrystalline UN were prepared from fully enriched uranium, and one cored pellet and ten wafer specimens of polycrystalline UN were prepared from depleted uranium. The UN powder was prepared by reacting nibbled* uranium metal with prepurified nitrogen gas in a reaction furnace that was evacuated to 1×10^{-6} torr before back filling with nitrogen. The reaction furnace contained tungsten heaters and shields and the nibbled uranium was contained in tungsten-lined molybdenum crucibles. To form the higher nitride powder, the nitrogen gas was maintained at 850°C and one atmosphere of pressure. When this reaction was completed, the temperature was slowly increased to 1400°C. The furnace was then evacuated to 1×10^{-5} torr to allow the powder to cool under a vacuum. Before removing the

* Uranium metal niblets are cubes ($\sim 1/8$ in.) which contain a minimum amount of contaminants for their surface area.

UN-containing crucibles from the furnace, the furnace was back filled with argon gas. The UN powder was then placed in a dry box, screened through an 80 mesh seive, vibrationally packed into rubber hydrostatic pressing tubes, and green pressed into rods under a pressure of 100,000 psi. The rods were sized, wrapped in tantalum foil and degassed graphite foil, and inserted in tantalum tubes which were subsequently sealed by electron beam welding tantalum plugs in the ends of the tubes. Densification of the UN rods was accomplished by hot isostatic compaction at a temperature of 1650°C and a pressure of 15,000 psi for three hours. The pressure was released at temperature and the rods were furnace cooled. Final sizing of the densified pellets was accomplished by electrical discharge drilling to 0.084 in. diameter followed by honing of the I.D. to 0.090 in. and grinding of the O.D. to 0.195 in. To prevent extensive fracturing while cooling in the hot isostatic pressing autoclave, each rod was densified considerably oversize. Thus, approximately 0.25 in. was removed from the O.D. of each rod. The depleted UN pellets were prepared before the enriched pellets.

Cladding and Hardware Preparation

Cladding tubes, which had been fabricated from solid TZM molybdenum alloy bar stock, were obtained from Thermo Electron Engineering Company, Woburn, Massachusetts. These tubes had been sized by grinding the O.D. and drilling the I.D. with a centercut gun drill.⁽⁹⁾ Use of a special lubricant, developed by Thermo Electron Engineering Company, eliminated the need for honing the I.D. The cladding was nondestructively tested and then machined to length.

End caps were machined from solid molybdenum bar stock. The plenum sleeves and the support rings were machined from swaged molybdenum tubing having a 0.25 in. (outside) diameter

and 0.050 in. wall thickness. Electrical discharge machining (EDM) was used to fabricate the tungsten wafers and springs from unalloyed tungsten foil.

Pin Assembly

All pin components (Figure 5 and 6) were thoroughly cleaned in acetone and ethanol and dried before assembly. The tungsten support sleeves were only used with cored pellets. Although not shown in Figure 5, plenum support rings and penum support sleeves of the type shown in Figure 6 were used in the pins containing UO_2 pellets as well as in the pins containing UN pellets. End caps without extensions, similar to those shown in Figure 5, were only used in fuel pins containing depleted fuel. End caps with extensions, similar to those shown in Figure 6, were used in fuel pins containing enriched fuel. The interior components, including the fuel pellets, were then inserted into the tubing. The assembly was placed in a welding box which was evacuated to 1×10^{-4} torr and backfilled with helium. The second end cap was welded into place, completing the fuel pin assembly (Figure 7).

EVALUATION OF THE FUEL PINS

Ceramic grade UO_2 was purchased to ASA N5.5 specification, issued September 20, 1965, by the American Standards Association, Inc. Analyses of the depleted and enriched UO_2 powder, as reported by the vendors, are shown in Table II. After processing the depleted and enriched UO_2 into pellets, the oxygen-uranium ratio (O/U), and flourine, chlorine, and water contents were determined (Table III).

The UN pellets were analyzed at the Battelle Memorial Institute Laboratories in Columbus, Ohio. Analyses of the UN pellets are shown in Table IV.

* Wt%

Metallographic samples of the UN pellet material were also taken at the Battelle Memorial Institute Laboratories in Columbus, Ohio. Typical microstructures of the depleted UN pellets are shown in Figure 8. Typical microstructures of the enriched UN pellets are shown in Figure 9 and 10. The white second phase visible in the microstructure, especially for pellets 5 and 6 (Figure 10), was not positively identified but has been occasionally observed in other uranium nitride specimens made from enriched uranium. The second phase is thought to be oxide, because the oxygen contents in pellets 5 and 6 are higher than in the other UN pellets (Table IV). However, this phase does not have the usual appearance of oxide inclusions. Recent irradiations by Battelle-Northwest with (U,Pu)N fuel containing 4000-5900 ppm oxygen indicates that the oxygen content in these fuel pins (340-875 ppm) should not adversely affect fuel performance (i.e., excessive grain growth or thermal decomposition at temperatures up to 2000°C).⁽¹⁰⁾ The nitrogen contents of the enriched pellets, as shown by chemical analyses (Table IV), are lower than the microstructures would indicate. Pellets 1 through 4 were used in pins 11, 12, 14, and 15, respectively, and contained uranium enriched to 93.17 per cent ²³⁵U. The uranium used for pellets 5 and 6 (pins 19 and 20) contained 93.10 per cent ²³⁵U.

The dimensions of all fuel pellets were accurately measured and the densities determined. Fuel column weights, dimensions, and densities for all of the fuel pins are shown in Table V.

All of the components of each pin were accurately weighed (Table VI), and the total weight of the components cross-checked with the weight of the assembled fuel pin. The weights agreed to within 0.1% for the prototype fuel pins

* Second end cap only

** Includes first end cap

containing depleted UO_2 pellets, and to within 0.02% for the remaining fuel pins.

Molybdenum tubing was purchased to the standard TZM alloy composition, i.e., 0.5% Ti, 0.08% Zr, and 0.02% C, bal.: molybdenum. Analysis of the TZM alloy is shown in Exhibit I. The cladding tubes were ultrasonically tested for internal defects using a 0.0026 in. deep by 0.015 in. long artificial defect as the reject level. Three of the original 20 pieces ordered were rejected. All pieces in a subsequent order were accepted. Wall thickness on all tubes, measured by micrometer at the tube ends and from radiographs, was uniform and within specifications. The dimensions of each component for each pin were checked. All dimensions conformed to the specifications shown on Drawings No. R-1008 (Figure 1) with the exception of the diameters of the solid depleted UO_2 pellets which were 0.188 in. and the inner diameters of the hollow depleted UO_2 pellets which were 0.086 in. These exceptions were inconsequential to the evaluation planned for the prototype pins and were accepted by NASA-Lewis.

The end caps were fabricated from unalloyed molybdenum. Fourteen end caps (Part 30, Figure 1) were supplied by NASA-Lewis for the fuel pins containing enriched UO_2 pellets. All other end caps were fabricated by Battelle-Northwest Laboratories from bar stock supplied by NASA-Lewis. No special significance is implied to either the part number, the supplier, or the fabricator; this point is documented only in the event that subsequent evaluation should detect a difference between the sources of material. An analysis which is representative of the unalloyed molybdenum used for the end caps is shown in Exhibit II.

EXHIBIT II. Analysis of Molybdenum Bar Stock

All tungsten parts were fabricated from unalloyed tungsten foil.

After final closure welding, the pins were checked for leaks with a helium leak detector. The pins were radiographed to determine weld penetration and fuel column integrity and location. Photographic prints made from radiographs of the fuel pins are shown in Figures 11, 12, and 13. Complete weld penetration was obtained on all pins. The minimum wall thickness in the weld regions was 75% of the specified tube wall thickness in all pins. Inversion of the tungsten Belleville spring was detected in fuel pin No. 39. Because the inverted spring will not affect the performance of the fuel pin, the pin was not disassembled.

PROBLEMS ENCOUNTERED DURING FABRICATION

Several difficult and time consuming problems were encountered in fabricating these fuel pins. The experience gained in solving these problems may be of value in fabricating other types of high temperature fuel pins or related fuel assembly components. For this reason, a brief discussion of these problems and their solution is presented. It will be of interest to note that the problems described were all associated with the cladding or end caps. No significant problems were encountered in fabricating the fuel pellets.

Considerable effort was expended in attempting to obtain the thin wall (0.025 in.) molybdenum cladding originally specified for the fuel pins. Stock molybdenum tubing, made by powder metallurgy, was available in the proper outside diameter, but the wall thickness was 0.050 in. Attempts to bore out this tubing met with many difficulties. The as-fabricated tubing cracked during machining; annealing

FIGURE 13. Radiograph of Assembled Fuel Pins Containing UN Pellets

alleviated this problem. Early machining attempts failed to hold wall thickness requirements, and although steady progress was made, the starting variation in wall thickness was too large to overcome by machining and the wall thickness reject rate remained high. In addition, a large percentage of the tubes were rejected for internal defects.

One lot of stock molybdenum tubing having a 0.250 in. (outside) diameter and 0.030 in. wall thickness, also a powder metallurgy product, was obtained and evaluated. Excessive cracking was detected in the tubing with the ultrasonic test, and no further work with this tubing was attempted.

These two types of tubing had not been fabricated by the vendors for nuclear fuel cladding. Consequently, they were not subjected to the strict quality control required for such use.

In view of these problems, NASA-Lewis specified that the wall thickness be increased to 0.050 in. With the adoption of the thick wall (0.050 in.) tubing, weld penetration became a problem. With the 0.025 in. wall tubing, 100% weld penetration was achieved, but with the 0.050 in. wall tubing, penetration in the test welds was between 50 and 60 per cent. Welding techniques were developed for the enriched UO_2 fuel pins with the goal of 80 per cent minimum penetration. The problem centered around the end cap design. The end cap contained a stem which restricted the electrode position. This restriction, in turn, limited the ability to apply to the proper location the amount of heat required to simultaneously melt approximately equal volumes of the end cap and can wall.

By relieving the diameter of the stem 0.015 in. and positioning the 1/16 in. diameter tungsten electrode at a 45° angle to the outer edge of the cladding, 80% penetration was achieved using 85 amperes and a welding speed of 7 rpm. Weld penetration varied between 50 and 60 per cent by the other technique investigated. By increasing the current to 90 amperes, complete penetration (100 per cent) was obtained on the fuel pins, themselves.

During final weld closure of the enriched UN fuel pins, the angle of the electrode was less than 45° and molten metal relocated to the small diameter region of the end caps. The unacceptable pins were reclad with new cladding and end caps.

The welding problem was corrected by increasing the angle of the tungsten electrode, thereby directing more heat into the weld region. Complete penetration was obtained on the acceptable enriched UN fuel pins. The minimum wall thickness in the weld regions of all pins was 75% of the tube wall thickness.
